

# Name : Mostafa Mohamed Abd Elatif Elelemy

## JavaScript Assignment – Lecture 1

Instructions: Answer all questions. Write code where required and explain your answers clearly.

### Part 1: Variables and Scope

#### **1. Explain how var works in JavaScript. What is variable hoisting? Give a code example.**

var: is a way to declare a variable

```
var num = 10;
```

Hoisting : moves all declarations to the top

```
var num
```

```
console.log(num); //will print undefined
```

```
var num = 10; //the initialization here
```

#### **2. What is the scope of a variable declared with var inside a function? What about inside a block (e.g., an if statement)?**

the scope of variable is local inside the function

and if it is in a block like (if) it stays global scope

**3. List all JavaScript primitive types in ES5. Give an example of each.**

num :> var age = 26;

string :> var name = "mostafa";

boolean :> var isnan = true;

undefined :> var num ;

console.log(num);

null :> var data = null;

console.log(typeof data);

**4. What is the difference between a primitive type and an object type? Give an example where this difference is important.**

primitive type like string is simple and immutable values

ex: var str = "hola";

str[0] = "H";

console.log(str); / it will print hola not Hola

object type is more complex and reference like array and function

**5. Create a number, string, and boolean using both literal and constructor syntax. Show the difference in their types using typeof.**

literal syntax :>

```
var num = 10
```

```
var str = "mostafa"
```

```
var isnan = true
```

constructor syntax

```
var num = new Number(32)
```

```
var str = new String("mostafa")
```

```
var isnan = new Boolean(true)
```

**6. Why is it generally recommended to use literals instead of constructors for primitive types?**

Because the literals is lightweight, fast, and simple.

**7. Given the following code, what will be the output? Explain why.**

```
var x = 123.4567;
```

```
console.log(x.toFixed(2)); // return 2 decimal places (as a string)
```

```
console.log(x.toPrecision(4)); // fix the total number to 4 and print it as string
```

**8. What is NaN? How can you check if a value is NaN? Give an example.**

Is not a number

To check we use isNaN

```
Ex :> var result = "hola" * 5;
```

```
console.log(result);
```

**9. What is the difference between parseInt, parseFloat, and Number? Give an example for each.**

Parseint : convert string to an integer

Ex :> var some = parseInt("3242,231");

Console.log(some);

parseFloat : convert string to float

ex :> var some= parseFloat("123.45px");

console.log(some);

number : convert the entire string

ex:> var some = Number("232.424");

console.log(some);

**10. What is the difference between implicit and explicit type casting? Give an example of each.**

is when converting a value from type to another

Implicit it done automatically by js

Ex :> var result = "10" + 5;

Console.log(result);

Explicit : in this is done manually by me using function like parsint and parsefloat

Ex :> var str = "10";

var num = parseInt(str);

console.log(num + 5);

**11. What will be the result and type of the following expressions? Explain your answer.**

- `true + 5` :> 5

- `"10" - 2` :> 8

- `12 - "1a"` :> NaN

- `5 / 0` :> infinity

- `5 + undefined` :> NaN

**12. What will be logged to the console in the following code? Explain each step.**

```
var a = "15.5"; // let it to be string
```

```
var b = +a; // convert it to number
```

```
console.log(b, typeof b); // print it and the type of it
```

it will print (15.5 'number')

explain because + convert it to number

**13. What will be the output of:**

```
var result = 20 > true < 5 == 1;
```

```
console.log(result);
```

it will print true

Explain why. because every condition(step) get true

14. Write a function that takes a string and returns true if it can be converted to a valid number, and false otherwise.

```
js.js > validNumber
1  function validNumber(str) {
2      var num = Number(str);
3      return !Number.isNaN(num);
4  }
5
6  console.log(validNumber("16723"));
7  console.log(validNumber("3.1874"));
8  console.log(validNumber("-0.5"));
9  console.log(validNumber(""));
10 console.log(validNumber("ab577c"));
11 console.log(validNumber("76fg3abc"));
12 console.log(validNumber(" "));
13 console.log(validNumber("0x11"));
```

15. Write a program that prints all numbers from 1 to 20 using a while loop.

```
js.js > ...
1  var num = 1;
2  while (num <= 20) {
3      console.log(num);
4      num++;
5  }
```

16. Write a program that asks the user to enter numbers until they enter 0, using a do...while loop. After the loop ends, print the sum of all entered numbers (excluding 0).

```
js js> ...
1   var sum = 0;
2   var number;
3
4   do {
5       number = Number(prompt("Enter a number (0 to show result):"));
6       if (number !== 0) {
7           sum += number;
8       }
9   } while (number !== 0);
10
11  console.log("The total sum is:", sum);
```

17. Write a program that takes a number from 1 to 7 and prints the corresponding day of the week using a switch statement. Use a for loop to test your program with all numbers from 1 to 7.

```
js.js > DayName
1  function DayName(dayNumber) {
2      switch (dayNumber) {
3          case 1:
4              console.log("Sunday");
5              break;
6          case 2:
7              console.log("Monday");
8              break;
9          case 3:
10             console.log("Tuesday");
11             break;
12         case 4:
13             console.log("Wednesday");
14             break;
15         case 5:
16             console.log("Thursday");
17             break;
18         case 6:
19             console.log("Friday");
20             break;
21         case 7:
22             console.log("Saturday");
23             break;
24         default:
25             console.log("Invalid number");
26     }
27 }
28
29 for (var i = 1; i <= 7; i++) {
30     console.log("Day " + i + ":");
31     DayName(i);
32 }
```
